The NAS Parallel Benchmarks (NPB) are a set of programs in order to evaluate the performance of parallel computers. The benchmarks are derived from computational fluid dynamics and they consist of five kernels and three applications. NAS Parallel Benchmarks are executed on Grid'5000.

References

- EP, this code implements the random-number generator. The code is “embarrassingly” parallel in that no communication is required for the generation of the random numbers itself. There is no special requirement on the number of processors used for running the benchmark.
- FT, this code implements the time integration of a three-dimensional partial differential equation using the Fast Fourier Transform.
- Data Traffic benchmark DT is written in C. DT benchmark takes one argument: BH, WH, or SH. This argument specifies the communication graph Black Hole, White Hole, or SHuffle respectively.
- LU, a regular-sparse, block (5 × 5) lower and upper triangular system solution. This problem represents the computations associated with the implicit operator of a newer class of implicit CFD algorithms.

Overhead
comparison of
Scalasca and
TAU

References

There are 7 classes at the NAS: W,S,A,B,C,D,E. Each one represent the size of the problem (input data).

- The W,S are very small classes.
- The A,B classes are used for a small number of processors.
- The C,D classes are used for executing big benchmarks.
- The class E is for huge benchmarks

- Tuning and Analysis Utilities
- Profiling and tracing toolkit for performance analysis of parallel programs written in C, C++, Fortran, Java and Python.
- Support for multiple parallel programming paradigms: MPI, Multi-threading, Hybrid.
- Access to hardware counters.
- Automatically instruments your code.
- Implemented by University of Oregon

The screenshot shows the TAU: ParaProf Manager application window. The title bar reads "TAU: ParaProf Manager". The window has a menu bar with "File", "Options", and "Help".

On the left side, there is a tree view under "Applications". It shows a folder "Standard Applications" containing "Default App" and "Default Exp". Under "Default Exp", there is a folder for the path "/home/lyon/gmarkomanolis/nas/NPB3.3/w/tau/". Inside this folder, two files are listed: "GET_TIME_OF_DAY" and "PAPI_FP_OPS", both with green status icons.

On the right side, there is a table with two columns: "TrialField" and "Value".

TrialField	Value

■ Pros

- Visualizing MPI calls is great help
- User can identify message sizes, time taken
- Automatic selective instrumentation
- Communication Matrix
- Tools for visualizing many useful data, save experiments to databases
- Memory tracking
- TAUCuda is on the way

■ Cons

- No automatic recognition of bottlenecks
- Large trace files for visualising.
- Slow tracefile reading
- Bad structure of output file format

- Scalable Performance Analysis of Large-Scale Applications
- Profiling and tracing toolkit for performance analysis of parallel programs written in C, C++, Fortran.
- Profile analysis.
- Time-line analysis (trace)
- Automatic identification of bottlenecks
- Pattern analysis
- Automatically instruments your code.
- Implemented by Julich Supercomputing Centre

- Scalasca does not support selective instrumentation as TAU, it is possible to declare only the functions that should be excluded.
- The good news is that it will be available soon and it will be implemented like TAU, using PDT for automatic instrumentation.

N x N Completion Time

Description:

This pattern refers to the time spent in MPI n-to-n collectives after the first process has left the operation.

Note that the time reported by this pattern is not necessarily completely waiting time since some processes could -- at least theoretically -- still communicate with each other while others have already finished communicating and exited the operation.

Wait at $N \times N$ Time

Description:

Collective communication operations that send data from all processes to all processes (i.e., n-to-n) exhibit an inherent synchronization among all participants, that is, no process can finish the operation until the last process has started it. This pattern covers the time spent in n-to-n operations until all processes have reached it. It applies to the MPI calls `MPI_Reduce_scatter()`, `MPI_Allgather()`, `MPI_Allgatherv()`, `MPI_Allreduce()`, `MPI_Alltoall()`, `MPI_Alltoallv()`.

Note that the time reported by this pattern is not necessarily completely waiting time since some processes could -- at least theoretically -- already communicate with each other while others have not yet entered the operation.

Late Broadcast Time

Description:

Collective communication operations that send data from one source process to all processes (i.e., 1-to-n) may suffer from waiting times if destination processes enter the operation earlier than the source process, that is, before any data could have been sent. The pattern refers to the time lost as a result of this situation. It applies to the MPI calls `MPI_Bcast()`, `MPI_Scatter()` and `MPI_Scatterv()`.

References

- the command `cube3_diff name1.cube name2.cube` , creates a `diff.cube` file with the difference of both cube files.
- `cube3_cut -r ' << phase >>' name.cube` creates a cube with the phase sub-tree.

References

■ Pros

- Parallel analyzer SCOUT
- Automatic recognition of bottlenecks
- A new release will be available during SC '09 with many upgrades.
- Very good structure of the output file format.

■ Cons

- Limited selective instrumentation
- No Communication Matrix
